HEIDELBERG LAUREATE FORUM

# Logic and Al

- Would like our AI to have knowledge about the world, and logically draw conclusions from it
- Search algorithms generate successors and evaluate them, but do not "understand" much about the setting
- Example question: is it possible for a chess player to have all her pawns and 2 queens?
  - Search algorithm could search through tons of states to see if this ever happens, but...

# Syntax

- What do well-formed sentences in the knowledge base look like?
- A Backus-Naur Form (BNF) BNF grammar:
- $Symbol \rightarrow P, Q, R, ...,$
- Sentence → True | False | Symbol | NOT(Sentence) | (Sentence AND Sentence)
   | (Sentence OR Sentence) | (Sentence => Sentence)
- We will drop parentheses sometimes, but formally they really should always be there

#### **Semantics**

- A model specifies which of the proposition symbols are true and which are false
- Given a model, I should be able to tell you whether a sentence is true or false
- Truth table defines semantics of operators:
- Given a model, can compute truth of sentence recursively with these

а	b	NOT(a)	a AND b	a OR b	a => b
false	false	true	false	false	true
false	true	true	false	true	true
true	false	false	false	true	false
true	true	false	true	true	true

#### Basic terms

- A valid sentence or tautology is a sentence that is True under all interpretations, no matter what the world is actually like or how the semantics are defined. Example: "It's raining or it's not raining."
- An **inconsistent sentence** or **contradiction** is a sentence that is False under all interpretations. The world is never like what it describes, as in "It's raining and it's not raining."
- Pentails Q, written P = Q, means that whenever P is True, so is Q. In other words, all models of P are also models of Q.
- TwoIsAnEvenNumber OR ThreeIsAnOddNumber
  - is true (not exclusive OR)
- TwoIsAnOddNumber => ThreeIsAnEvenNumber
  - is true (if the left side is false it's always true)

All of this is assuming those symbols are assigned their natural values...

# **Tautologies**

- A sentence is a tautology if it is true for any setting of its propositional symbols
- (P OR Q) OR (NOT(P) AND NOT(Q)) is a tautology

Ī	Р	Q	P OR Q	NOT(P) AND	(P OR Q)
				NOT(Q)	OR (NOT(P)
					AND
					NOT(Q))
	false	false	false	true	true
	false	true	true	false	true
	true	false	true	false	true
	true	true	true	false	true

# Logical equivalences

- Two sentences are logically equivalent if they have the same truth value for every setting of their propositional variables
- P OR Q and NOT(NOT(P) AND NOT(Q)) are logically equivalent
- Tautology = logically equivalent to True

Р	Q	P OR Q	NOT(NOT(P)
			AND NOT(Q))
false	false	false	false
false	true	true	true
true	false	true	true
true	true	true	true

# Famous logical equivalences

- $(a OR b) \equiv (b OR a)$  commutativity
- $(a \text{ AND b}) \equiv (b \text{ AND a})$  commutativity
- $((a \text{ AND b}) \text{ AND c}) \equiv (a \text{ AND (b AND c}))$  associativity
- $((a OR b) OR c) \equiv (a OR (b OR c))$  associativity
- $NOT(NOT(a)) \equiv a$  double-negation elimination
- $(a => b) \equiv (NOT(b) => NOT(a))$  contraposition
- $(a => b) \equiv (NOT(a) OR b)$  implication elimination
- NOT(a AND b)  $\equiv$  (NOT(a) OR NOT(b)) De Morgan
- NOT(a OR b)  $\equiv$  (NOT(a) AND NOT(b)) De Morgan
- $(a \text{ AND } (b \text{ OR } c)) \equiv ((a \text{ AND } b) \text{ OR } (a \text{ AND } c))$  Distributivity
- (a OR (b AND c))  $\equiv$  ((a OR b) AND (a OR c)) Distributivity

# Reasoning patterns

- Obtain new sentences directly from some other sentences in knowledge base according to reasoning patterns
- If we have sentences a and a => b, we can correctly conclude the new sentence b
  - This is called modus ponens
- A **Horn sentence** or **Horn clause** has the form:

$$P1 \land P2 \land P3 \dots \land Pn \rightarrow Qm \text{ where } n \ge 0, m \text{ in } \{0,1\}$$

- If we have a AND b , we can correctly conclude a
- All of the logical equivalences from before also give reasoning patterns

$$(P \rightarrow Q) = (\neg P \lor Q)$$

# Propositional logic (zeroth-order logic)

- Logical constants: true, false
- Propositional symbols: P, Q, S, ... (atomic sentences)
- Wrapping **parentheses**: ( ... )
- Sentences are combined by **connectives**:

```
∧ ...and [conjunction]
∨ ...or [disjunction]
⇒ ...implies [implication / conditional]
⇔ ...is equivalent [biconditional]
¬ ...not [negation]
```

• Literal: atomic sentence or negated atomic sentence

# Examples of PL sentences

- User defines a set of propositional symbols, like P and Q.
- User defines the **semantics** of each propositional symbol:
  - P means "It is hot"
  - Q means "It is humid"
  - R means "It is raining"
- $(P \land Q) \rightarrow R$ "If it is hot and humid, then it is raining"
- Q → P"If it is humid, then it is hot"

# Propositional logic (PL)

- A simple language useful for showing key ideas and definitions
- A sentence (well formed formula) is defined as follows:
  - A symbol is a sentence
  - If S is a sentence, then  $\neg$ S is a sentence
  - If S is a sentence, then (S) is a sentence
  - If S and T are sentences, then  $(S \vee T)$ ,  $(S \wedge T)$ ,  $(S \rightarrow T)$ , and  $(S \leftrightarrow T)$  are sentences
  - A sentence results from a finite number of applications of the above rules

## A BNF grammar of sentences in propositional logic

# Modus ponens

- The form of a modus ponens argument resembles a syllogism, with two premises and a conclusion:
  - If P, then Q.
  - P.
  - Therefore, Q.
- It is a deductive argument form and rule of inference. It can be summarized as "P implies Q. P is true. Therefore Q must also be true."

# Modus ponens Example

- for all x: Loves(John, x)
  - John loves every thing
- for all y: (Loves(y, Jane) => FeelsAppreciatedBy(Jane, y))
  - Jane feels appreciated by every thing that loves her
- Can infer from this:
  - FeelsAppreciatedBy(Jane, John)
- Here, we used the substitution  $\{x/Jane, y/John\}$ 
  - Note we used different variables for the different sentences
- General UNIFY algorithms for finding a good substitution

#### Sound rules of inference

- Here are some examples of sound rules of inference
  - A rule is sound if its conclusion is true whenever the premise is true
- Each can be shown to be sound using a truth table

RULE	PREMISE	CONCLUSION
Modus Ponens	$A, A \rightarrow B$	В
And Introduction	A, B	$A \wedge B$
And Elimination	$A \wedge B$	A
Double Negation	$\neg \neg A$	A
Unit Resolution	$A \vee B, \neg B$	A
Resolution	$A \vee B, \neg B \vee C A \vee C$	

# Soundness of modus ponens

A	В	$A \rightarrow B$	OK?
True	True	True	<b>√</b>
True	False	False	<b>√</b>
False	True	True	<b>√</b>
False	False	True	<b>√</b>

# Example

- Consider the problem of representing the following information:
  - Confucius is a person.
  - Every person is mortal.
  - Confucius is mortal.
- How can these sentences be represented so that we can infer the third sentence from the first two?
- In PL we have to create propositional symbols to stand for all or part of each sentence.
  - R = "Confucius"; P = "person"; Q = "mortal";
  - so the above 3 sentences are represented as:
  - $R \rightarrow P; P \rightarrow Q; R \rightarrow Q$
- Although the third sentence is entailed by the first two, we needed an explicit symbol, R, to represent an individual, Confucius, who is a member of the classes "person" and "mortal"
- To represent other individuals we must introduce separate symbols for each one, with some way to represent the fact that all individuals who are "people" are also "mortal"

# Propositional logic is a weak language

- Hard to identify "individuals" (e.g., Mary, 3)
- Can't directly talk about properties of individuals or relations between individuals (e.g., "Bill is tall")
- Generalizations, patterns, regularities can't easily be represented (e.g., "all triangles have 3 sides")
- First-Order Logic (abbreviated FOL or FOPC) is expressive enough to concisely represent this kind of information

FOL adds relations, variables, and quantifiers, e.g.,

- "Every elephant is gray":  $\forall x (elephant(x) \rightarrow gray(x))$
- "There is a white alligator":  $\exists x (alligator(X) \land white(X))$

# Limitations and Problems of propositional logic

- No notion of objects
- No notion of relations among objects
- Some English statements are hard to model in propositional logic.
- Zeroth-order logic (Propositional Logic) is
  - first-order logic without variables or quantifiers.

# First-order logic

- First-order logic (FOL) models the world in terms of
  - Objects, which are things with individual identities
  - Properties of objects that distinguish them from other objects
  - Relations that hold among sets of objects
  - Functions, which are a subset of relations where there is only one "value" for any given "input"
- Examples:
  - Objects: Students, lectures, companies, cars ...
  - Relations: Brother-of, bigger-than, outside, part-of, has-color, occurs-after, owns, visits, precedes, ...
  - Properties: blue, oval, even, large, ...
  - Functions: father-of, best-friend, second-half, one-more-than ...

# Reasoning about many objects at once

- Variables: x, y, z, ... can refer to multiple objects
- New operators "for all" and "there exists"
  - Universal quantifier and existential quantifier
- for all x: CompletelyWhite(x) => NOT(PartiallyBlack(x))
  - Completely white objects are never partially black
- there exists x: PartiallyWhite(x) AND PartiallyBlack(x)
  - There exists some object in the world that is partially white and partially black

#### Inference rules

- Logical inference is used to create new sentences that logically follow from a given set of predicate calculus sentences (KB).
- An inference rule is **sound** if every sentence X produced by an inference rule operating on a KB logically follows from the KB. (That is, the inference rule does not create any contradictions)
- An inference rule is **complete** if it is able to produce every expression that logically follows from (is entailed by) the KB. (Note the analogy to complete search algorithms.)

# Limitations of First-Order Logic

- We are **not** allowed to reason in general about relations and functions
- We need higher-order logic (which is more powerful).
- "If a property is inherited by children, then for any thing, if that property is true of it, it must also be true for any child of it"
- Axioms: basic facts about the domain, our "initial" knowledge base
- Theorems: statements that are logically derived from axioms

# Thinking Rationally

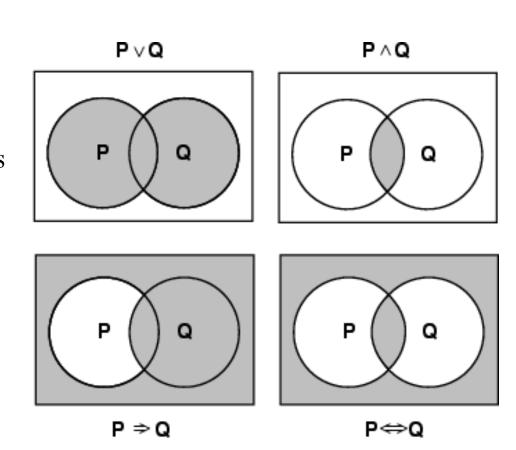

- **Right Thinking:** "arguments structures that always gave correct conclusions given correct premises"
- Syllogism: "Socrates is a man; all men are mortal therefore Socrates is mortal."
- Field of Logic: Laws of thought were supposed to govern the operation of the mind.
  - Logical notation to find solution to a problem.
  - Finding solution to all kinds of things in the world and the relations between them.
- **Issue 1:** Not easy to take informal knowledge and state it in the formal terms required by Logical notation, particularly when the knowledge is less than 100% certain.
- **Issue 2:** There is a big difference between being able to solve a problem "in principle" and doing so in practice. Means proposing algorithm and it's coding are different problems.
- Power of the representation and reasoning systems

# Machine Acting V/S Thinking?

- Weak AI Hypothesis vs. Strong AI Hypothesis
  - Weak Hyp: machines could act as if they are intelligent
  - Strong Hyp: machines that act intelligent have to think intelligently too
- Hypothesis:
  - "a supposition or **propos**ed explanation made on the basis of limited evidence as a starting point for further investigation"
  - "a proposition made as a basis for reasoning, without any assumption of its truth"
- Machine learning:
  - "algorithms to build model using data for training, which makes machine capable enough to make **predic**tions or decisions without being explicitly programmed"
- What is Machine learning Hypothesis?

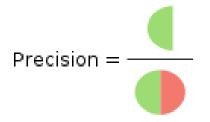

# Models of complex sentences

- The meaning or **semantics** of a sentence determines its **interpretation**.
- Given the truth values of all symbols in a sentence, it can be "evaluated" to determine its **truth value** (True or False).
- A **model** for a KB is a "possible world" (assignment of truth values to propositional symbols) in which each sentence in the KB is True.

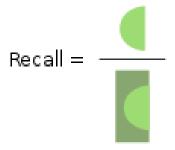

#### **Precision and Recall**

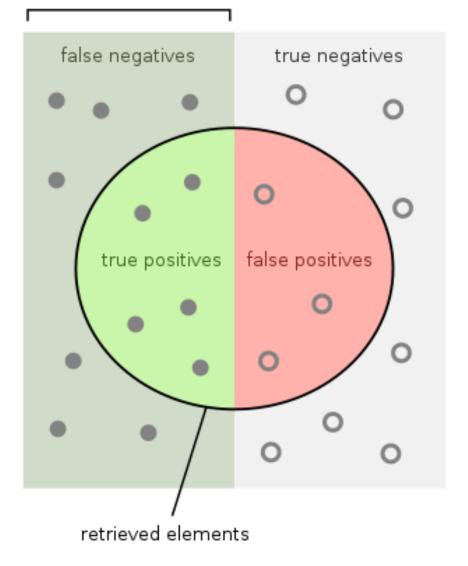

How many retrieved items are relevant?

How many relevant items are retrieved?

#### relevant elements

#### **Precision and Recall**

- A set of retrieved documents
  - (e.g. the list of documents produced by a web search engine for a query)
- A set of relevant documents
  - (e.g. the list of all documents on the internet that are relevant for a certain topic)

```
precision = \frac{|\{relevant\ documents\} \cap \{retrieved\ documents\}|}{|\{retrieved\ documents\}|}
```

$$recall = \frac{|\{relevant\ documents\} \cap \{retrieved\ documents\}|}{|\{relevant\ documents\}|}$$

# Summary

- The process of deriving new sentences from old one is called **inference**.
  - **Sound** inference processes derives true conclusions given true premises
  - **Complete** inference processes derive all true conclusions from a set of premises
- A **valid sentence** is true in all worlds under all interpretations
- If an implication sentence can be shown to be valid, then—given its premise—its consequent can be derived
- Different logics make different **commitments** about what the world is made of and what kind of beliefs we can have regarding the facts
  - Logics are useful for the commitments they do not make because lack of commitment gives the knowledge base engineer more freedom
- Propositional logic commits only to the existence of facts that may or may not be the case in the world being represented
  - It has a simple syntax and simple semantics. It suffices to illustrate the process of inference
  - Propositional logic quickly becomes impractical, even for very small worlds
